The following observations on the identity of fever and the treatment of its various forms are respectfully submitted to the Faculty of the University of Pennsylvania, in obedience to the laws of that Institution.

I have chosen this subject knowing it to be a difficult question, and one which has employed much of the learning and talent of the Medical Profession, even from the times of Hippocrates. — Nor have we yet succeeded in pointing out the causes, locality, & treatment of different phenomena produced by febrile agents and exhibited in the course of disease. — So long as there is a discrepancy of opinion among authors, with regard to any subject, all cannot be right.

If there men, who are endowed with superior mental ability & who have had the advantage of a well regulated course of instruction, who have enjoyed every opportunity for the cultivation of the science of Medicine, connected with the most extensive Hospitals,

The first of the month of January  
was a day of great beauty and  
the sun shone brightly upon the  
snow-covered hills and fields.  
The wind was fresh and cold  
and the air was clear and bright.  
The snow was deep and soft  
and the hills were covered with  
a thick layer of white.  
The fields were covered with  
a thick layer of white and the  
trees were covered with a thick  
layer of white. The hills were  
covered with a thick layer of  
white and the fields were covered  
with a thick layer of white.  
The trees were covered with a  
thick layer of white and the  
hills were covered with a thick  
layer of white. The fields were  
covered with a thick layer of  
white and the trees were covered  
with a thick layer of white.

Exposures and Armies, and in the most sickly parts of the world, disagree as to the nature and origin, and locality of the febrile agent, the different laws which modify its action; if men endowed with the noblest faculties of human nature, who have shed a light on every other branch of the science, yet have not been able, with their united genius, & applications, to illustrate this subject, it may appear vain in me to attempt a solution of the difficulty, or to throw an additional light on this obscure point in Medical Science.

Without indulging such a hope, I have chosen this subject, more with a view of making myself more thoroughly acquainted with it than I would otherwise become. I am fully convinced that I cannot make myself too fully acquainted with all that relates to it, and this, it is hoped will be a sufficient excuse, (if any be necessary) for my present attempt to grasp at things beyond my reach.

The successive hypotheses prevailing through a long period of Medical history, have been numerous;

and they present to us fanciful notions, more crude and visionary than the opinions of the ancients generally with regard to other subjects.

They lived at a period called, by them, the scientific age, but by us the morn or dawn of science; and we imagine we have arrived at the meridian splendour of science, but may not the lapse of a few centuries expose the falling of principles now deemed incontrovertible? There is a possibility of this; let us not, therefore, censure our predecessors too severely, let us be content in our turn. — The agent producing febrile affections is now thought to be produced by a decomposition of animal & vegetable matter, from the circumstances of fevers being more prevalent in those districts where animal and vegetable matter are undergoing a decomposition: we attribute it to this cause; but of its existence we have no knowledge, with the exception of the effects which it produces. As to its constituent or elementary principles

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

*[Faint, illegible handwriting on the right edge of the page, likely bleed-through from the reverse side.]*

we are ignorant, and what we take for granted is, that a noxious ethereal fluid is generated. It is said by some, miasmata may be generated from a variety of sources, but this I am not willing to admit: for if we take into consideration that the constituent and elementary principles of the earth are few in number, we shall find that there are but few resources for the origin of this peculiar compound.

Miasma is a generic term meaning a generated ethereal fluid, which, when applied to the system, under peculiar conditions, is capable of producing febrile affections. - By some it is thought that stagnant water produces Miasma; but we know that water is indestructible and cannot be any thing more or less than an agent, or medium, in the production of Miasma. It is necessary that a certain degree of moisture and heat exist at the same time for the production of this noxious vapour: -

We know that it is well ascertained that most, if not all, kinds of vegetable matter, when deprived

*[Faint, illegible handwriting on lined paper, likely bleed-through from the reverse side.]*

*[Faint, illegible handwriting on the right edge of the page, likely bleed-through from the reverse side.]*

of their water by baking, or by any other process & kept perfectly dry, will remain undecomposed, for an indefinite time. — There are other cases in which organic matter is much more susceptible of decomposition & in which moisture & a common degree of temperature are sufficient to resolve them into their constituent principles, or to change the order of their compounds & produce new compounds.

It must be evident to every one that the evaporation of pure water cannot prove noxious to a healthy system, as is proved by the evaporation which takes place during winter, at this season there is little or no animal or vegetable matter undergoing decomposition, as the heat at this time is not capable of exerting decomposing influence. — The atmosphere at this time is loaded with aqueous vapour. Evaporation takes place from the large lakes and from the surface of the Ocean & no fever is engendered by inhaling the atmosphere at such a distance from the shore that the sea and land air cannot be mingled. — It is also pretty evident that the decomposition of vegetable matter

alone, is not always a source of fever. - Let us for  
a moment consider the immense quantity of luxuriant  
foliage annually clothing the forest which at the approach of  
autumn leaves its verdure and undergoes decay & rot,  
which alone would produce fevers all over the world,  
were it capable of so doing without the aid of the large  
quantity of other vegetable matter which, under the most  
favourable circumstances, combined with a softness of  
moisture & aided by a scorching sun, as we see in the pome-  
yards, without being able to excite fevers. If vegetable  
decomposition alone could produce this effect, we would  
necessarily have fevers in their most malignant forms  
in every forest and every farm at the approach of  
summer. We know that no people are more exempt  
from febrile affections than our forest inhabitants, much  
from situations where agriculture is extensively practised.

It is also very conclusive that the decomposition of  
animal matter is incapable of generating this noxious  
ague, & as a demonstrative proof of this we may cite  
the experiments conducted under the direction of

Thermost) of the public burial ground, situated in one of the most frequented & populous parts of Paris, which had been one of the depositories of dead bodies, until the earth had become elevated six or eight feet above the common level and literally the dead were buried in the dead. The ground became so much frequented with putrefying human remains, that the exhalation from the ground became the source of public nuisance and excited in the minds of the people disgust & indignation. The police taking advantage of this public feeling determined on the removal of this superstratum of human deposit.

At the commencement, which took place in the latter part of Autumn & was continued during the winter & early part of Spring, the greatest caution was observed, but no accident took place, altho the labourers were almost stifled when breaking in upon a corpse, which had not undergone perfect decomposition, by the gas arising in a concentrated state. And in the latter part no great was paid to the season of the year, & any particular

caution observed & no fever was known to take place in any of the labours engaged in that enterprise.

As a further evidence I cite the report made by — Barthe, professor at Montpellier, & two of his colleagues at that University, who were sent by the convention of France, into Spain, to examine & report the nature of the Yellow Fever which had proved so fatal in several parts of Spain in 1800. — Being at Seville a few months after the epidemic had ceased, he states, in his report, that the burial ground in which the victims were placed is composed principally of clay, & the season being warm the ground cracked into wide & deep crevices through which fatal exhalations took place, in consequence of the decomposition which was going on in the mass of dead bodies.

Notwithstanding the large concourse of people that daily visited these burial grounds, some to gratify idle curiosity & others to testify their regard for departed friends. And after repeated examinations of the guards & grave-diggers stationed at these places, and from other sources, equally claiming our confidence, not a

case of "foul air" known to be the place in consequence  
of breathing this atmosphere impregnated with exha-  
lations of human decomposition. —

It also concludes to our mind that the chemical  
constituent of the Ferriol Glaciers is strong evidence  
as not to be acted upon by the combined influences of,  
a vertical sun & moisture without producing a  
substance evident to our senses and the chemist  
cannot detect it with all his resources.

It is true that the chemistry has never yet  
demonstrated the existence of Miasm, but it does not  
hence follow that such a principle does not exist. —

The hypothesis of its originating from decomposition  
conditions, or from the appearance of comets is altogether  
unfounded in any demonstrable facts with which we  
are cognized. — There occurs always known immedi-  
ately to precede or succeed the exhibition of these sub-  
terranean phenomena, or the approach of comets  
thus would be some plausibility in the hypothesis;  
but we know that this is not the case. We have

fevers where there are no volcanoes or earthquakes  
'or Comets & when these phenomena represent me,  
have no fevers & further, they do not exert any influence  
over, or aggravate the type of fever, or any epidemics  
prevailing at the time of their appearance. —

(These subterranean combustions capable  
of exciting fevers are showed here in Volcanic  
districts, in every variety & stage of aggravation marring  
the inhabitants with death released the victims. But  
we do not find this to be the case.

The composition of our planet and its products  
is far as we know, made of but a very few principles. But  
the composition of these simples to form a compound  
produces powerful & astonishing effects and it does appear  
that the compound produced by the union of these  
simples owes its peculiarity, or its noxiousness, or its  
salubrity in a direct ratio to the purity & quantity of the  
simples composing the compound. And by the  
union of these simples in different proportions with  
each other we have all the different forms and

variety of matter known to our senses and all this difference of variety & force in the property of matter depends on an union of <sup>parts</sup> simple & quantity to form compounds.

The question now arises, from whence does this peculiar agent take its origin? We have attempted to prove that it cannot be produced from the vegetable or animal Kingdom, or from the cooperation of pure water & the earth's component principles, the appearance of Comets, Lubrication combustion. &c. It must originate then in consequence of the combination & decomposition of the decomposition of mineral and vegetable matter induced by a sufficient quantity of moisture & heat.

We have, after much labour and patient investigation, we have obtained this peculiar agent in the excitation of fibres. But we have now a task equally difficult in carrying it through the different avenues & localizing it in the system & making it produce all the different forms of fever & phenomena attending them & when we have done this our way consists our tasks done. — All, I believe, agree in our particular

March 11

Dear Sir

I have the honor  
to receive your letter  
of the 10th inst.

and in answer  
to inform you  
that the same  
has been forwarded  
to the proper  
authorities for  
their consideration

namely, that it is necessary for its application to some part of the system in order that it shall produce its full effects.

Experiments prove that there are but two narrow avenues through which this agent can enter the system, viz: the mouth and nose, from thence to the lungs, becomes entangled with the saliva, whilst entangled in this passage & conveyed through the oesophagus to the stomach. Here I will take the liberty of representing the vile practice of taking snuff & plucking out the hairs which grow in the cavity of the nose. The hairs act an important part in the preservation of our health. They act the part of sentinels in preventing foreign matter from entering the lungs. If plucked out they fail to do this office, & if the owner of the nose is guilty of the vile practice of taking snuff, they become matted & perform their functions imperfectly.

We know that the sympathy existing between the lungs and stomach, & in fact all the system

is nothing in comparison to that which exists with regard to the stomach & alimentary tube. We know that a derangement of this canal affects the system more or less in proportion to the extent & duration of derangement.

Whereas, the lungs may be affected to a considerable extent & even the larger portion may be a mass of disease & still the health be but little affected; the patient's appetite & digestive organs are in a pretty healthy condition & perform their functions in a ~~regular~~ & natural manner; retaining his appetite & spirits to the last. It is true, he becomes pale, full & emaciated in the course of time, in consequence of the incapacity of the lungs in performing their functions. From this course of reasoning, we come to the conclusion, that it must be applied to the stomach, & from thence extending through the alimentary canal affecting the organs engaged in the process of assimilation & elaboration.

We now have this peculiar agent in the irritation of fumes located in the stomach and

alimentary tube... & quite new views with regard to its position & action on these organs. Does it not the part of a stimulant or that of a sedative with respect to the intestines? In the case of the latter opinion, from the effects just produced I must conclude it can be decided.

Now, in most instances, after the application of this agent in the excitation of fever, or sometimes below the mean temperature of a healthy system, some times more & some times less, with languor, listlessness of the mental & bodily energies, an inclination to think & stir from the recumbent posture, with more or less drowsiness, sometimes a disposition to sleep prevails, but is prevented by the freedom even of a morbid irritability which harasses the patient & makes him seek for sleep, after which he procures himself a speedy recovery from his embarrassing sensations. But after a short repose, a surmounting sleep, he awakes with more or less of his confusion of mind & tongue & finds one day, that more or less urgent, which he attempts to allay by taking

lance & respiratory draughts of cold & air. - Respiration becomes more & less hurried with some difficulty & loudly. The face is flushed, the eyes & a reddish misty hue, the mucous glands & stimulated to increase & are increased by an increased flow of blood. The heart is stimulated to increased action. The arteries thro' with more & less violence in proportion to the action of the heart.

The pulse is full & strong, bounding & chorded in proportion to the extent of local irritation, the intensity & sensibility of the point & the distance from the general centre of the sympathy, the stomach & alimentary canal, the healthy condition of which & its appendages are of more importance to the healthy condition of the system than any other organ, the liver, however, is not excited.

From this course of reasoning I am brought to the conclusion that all fevers originate from the same source & differ in <sup>other</sup> respect from each other, than the intensity & location & position. I believe that some fevers are gastro-enteric affections & affections of the organs below

ditionary to the stomach & alimentary tube. And what constitutes the varieties of fevers is the location, most intensity of affection & the different phenomena observed in relation to the intensity of the action of the organ affected & the sensibility of the seat of affection. We know that the indications of all fevers are nearly the same, and the similarity of their remedial agents supports this position.

In all fevers we have more or less nervous irritations in proportion to the concentration of the miasma, the time during which it is applied and the nature & extent of the surface to which it is applied. I have observed that it was my belief that the first impression on a system after the application of miasma, was that of diminished action in the heart. Progressively takes place in the first a consequent exhaustion in the vessels, then, next, comes congestion & inflammation in the stomach & perhaps to the intestinal surface affected.

We have no evidence that all fevers are not

1  
The same. We have no intention that the repetition  
excites intermittent or remittent, or that select & select  
Billious or Mellow fever. The fact is that one agent  
produces all the variety of fever, the location intensity of  
action in the part, extent of surface affected, the organ  
affected, & the conditions of the nervous system at the  
time of affection. If the nervous system is in a diseased  
condition, or disposed to take a diseased action, we shall  
have nervous irritation in a direct proportion to the  
quantity of diseased action existing in the nervous system.

We shall next inquire what disease is, and we  
shall find it to be an altered action in the part.

We are sensible of but two actions pervading  
the system, that of healthy and diseased, and every  
graduation from the healthy action constitutes a gradua-  
tion in the quantity of disease. (It I mean to express myself)

We will here ask the question, what is fever?  
& we shall find that it is nothing more or less than  
the effects produced by altered action in some par-  
ticular parts of the system. And their effects will be

in a direct proportion to the extent and intensity of diseased action, the sensibility of the part or organ affected and the number of organs or parts implicated in the disease.

During the latter part of spring, summer and the commencement of autumn, we have continued Bilious fevers. During this period the miasm is generated in more abundance & consequently becomes more concentrated & capable of exciting more intense impressions on the system.

Since the diseases are distinguished from each other by the part affected, & the intensity of the affection.

In continued fevers the Stomach is the seat of disease, in Yellow fever the Stomach & duodenum is the seat of affection, differing in no other respect from continued fever than in intensity & extent of diseased action, & in Bilious fever the Liver appears to be more immediately the seat of diseased action. During the latter part of autumn, winter & the early part of Spring we have Intermittents, remittents and Typhoid fevers.

This artificial division will not always hold

good, for in many instances we have Intermittent & Remittent fevers prevailing during the latter part of Spring, Summer & the commencement of autumn, but this variation can be accounted for satisfactorily by admitting that the miasma is not generated in a quantity sufficient to produce the highest grades of fever & we have no hesitation in admitting this fact.

It may not here be amiss to take a survey of the people inhabiting the northern regions of Europe. Who, during a period of five, six or eight months retire to winter quarters, which consist yards sunk to the depth of six or ten feet below the surface of the <sup>and</sup> earth, <sup>and</sup> thatched with canvas. Their apartments are small & each contains the members of from six families together with their stock of provisions which consists of deer's fish in various stages of putrefaction. No air is permitted to enter their dwelling, except through a small hole in the top. They have no fire to dry their food or keep themselves warm, but the necessary warmth is kept up by pulvis nary & cutaneous exhalation, a small lamp illuminates,

their habitations & here they eat, sleep & obey all the demands of nature, without the least restriction as to decency & what is astonishing, they enjoy good health & never complain of noxious atmosphere which they are constantly inhaling, notwithstanding they are exempt from malarious & typhus fevers. In accordance with the general belief, there should have typhus every winter. It does appear from the symptoms of typhus fever that it is produced by a different agent, but we cannot subscribe to this belief, as the same indications in the mode of treatment are obtained.

I cannot help subscribing, in some degree, to the Reverianian doctrine & all our remedial agents in the treatment of febrile affections, go typhus, that doctrine which he so ably inculcates.

We have but one object in view in the treatment of all febrile affections, that is to restore healthy action to the part affected and good government in the system.

As the arterial system is deranged in a direct ratio to the quantity of diseased action & the nervous irritation is in a direct ratio to the extent & intensity of diseased

action in the part or organ affected & the sensibility of the part affected; in the treatment of acute & local affections we are to be governed by the severity and intensity of the action. In affections merely the affects produced by diseased action & the different symptoms & phenomena observed to point out the seat of diseased action.

The most conspicuous agent in restoring arterial action & government in the system is the Lancing & cold affusions.

These, as observed by some, are only to be used at the acme of the hot stage, but I am of opinion that they are serviceable at any period of the hot stage, so long as the skin is hot & dry & at the this period I am not an advocate for their employment.

In all cases, in the application of our remedies due regard must be paid to the existing symptoms — Such in order as leeches, they gain their superiority over the Scarificator in point of convenience in applications we can apply them to any part of the system & in any number, and to parts where the Scarificator could not be used.

The Scarificator & cupping glass come next in order

and in some particulars enjoy an advantage over the latter in being applied nearer to the seat of the disease & by this means we are enabled to take blood from the diseased part, at a time when the strength of the system could not bear resection, & leeches enjoy an advantage over latter in this respect. In such in order, in the treatment of febrile affections, are the saline purgatives effervescent and demulcent draughts. If the stomach is much deranged & will justify an emetic a mild one may be given, but if the state of the stomach & the brain does not justify the employment of an emetic it never fails to prove a source of aggravation & the degree of aggravation is in proportion to the extent of derangement of the brain & stomach and the mild or drastic action of the medicine employed.

Enemata are of the greatest importance in producing alvine evacuations, when the stomach will not permit the introduction of cathartics. Stimulating enemata may act by revulsively establishing inflammation which acts by inviting to the part increased arterial & nervous action, and by this means the disease in the original part

is diminished & action & government are restored in the parts affected.

We have a diseased action generated in the part produced by continued stimulating enemata but the part affected is not disposed to continue the diseased action & as soon as we cease to apply stimuli the parts regain their healthy state.

Mercurial purgatives are of the greatest importance & are not to be neglected, they serve to establish functional action more specifically than any other agent with which we are acquainted. They also allay nervous irritations, in many diseases, more promptly than any other of our agents and particularly when given in combination with opium. We are to be governed here, as in every other case, by symptoms then prevailing in the system, in selecting & using our remedies.

We have a variety of agents for allaying arterial action & nervous irritations but we are to be governed in our selections by the symptoms and

51  
idiosyncrasy of the system in applying these agents and in  
regulating them to the proper extent, beyond which they may  
prove detrimental.

We are always to keep in view the alimentary  
tube & in the application of all our remedies to endeavor  
to restore health by action & government in those parts affected  
after which we employ a different class of agents in restoring  
the system to its former state of health. These are  
called tonics, from their agency in restoring a lost  
tone or strength to the suffering part, in the selection  
& employment of the remedies of this class, we must  
be governed, as usual, by the constitutional habits  
of the patient, the seat of the disease & other circum-  
stances, which it is unnecessary to detail.

With regard to the particular articles of the Materia  
Medica to which the preference should be given, no unexcep-  
tionable rule can be formed. Calomel is undoubtedly the  
best evacuant of bile which is accumulated in the  
stomach & duodenum in febrile cases. But the great  
facility with which some patients become salivated is

an objection, in some instances, to the repeated exhibition of this article. In such cases Calomel may be advantageously exhibited in combination with some vegetable cathartic such as jalap or rhubarb: castor oil also forms an excellent combination with Calomel in cases where the stomach is irritated & we desire a prompt catharsis.

Of emetics the preference should be given to the tartaric of antimony. The activity of this emetic is such that I would recommend the exhibition of it in small & repeated doses until the effect is produced, rather than to prescribe a single dose & depend on that to produce the whole effect, & no more than might be desirable. Blood-letting should be permitted in all cases in which there is inordinate arterial action.

These evacuations, viz emetics, cathartics & diaphoretics when justifiable, should be continued as long as any indications remain of unhealthy nature in the stomach & intestines. If the evacuations assume a healthy appearance & the pulse continues high (a case that does not often occur) it may be reduced by the lancet in these circumstances.

bathing is very useful, not only in promoting the cutaneous secretions, but also in assisting the operation of the cathartics & other evacuent medicines applied to the intestinal canal. In the exhibition of tonics, care must be taken that the stomach be prepared for their reception by being clear of acid secretions and free from morbid irritability. In hot climates & in cases in which the system has been much enfeebled by evacuations it may be necessary to exhibit tonics & stimuli before the febrile action has entirely disappeared. Under other circumstances, however, we will accomplish our ultimate object more satisfactorily by waiting for a perfect remission of the acutest symptoms before we exhibit a tonic. — As to the selection of a tonic we must be governed much by circumstances. We have many articles belonging to this class, among which it would be difficult to choose, without due regard to the idiosyncrasy of the patient & other circumstances which are always present in the eye of the practitioner. We also meet, almost daily, with cases in which the greatest

number of tonic medicines are rejected by the stomach, or affect the intestines in a pernicious manner.

I presume that I will be excused from entering into a detail of their several peculiarities & of the numerous cases in which they would be severally preferable. One remark, respecting their use appears to be too important to be neglected, viz: the tonics given for the purpose of restoring the system sometimes disappoint our expectations by inducing a debilitating diarrhoea (the peruvian barks particularly) or a constipation little less to be desired.

It is, therefore, necessary to watch their effects, and to be ready with the proper remedies for the several influences which they may exert on the alimentary canal.

It is not necessary to remind the learned Faculty to whose judgment these remarks are submitted, that the limits of a thesis are too narrow for a full exposition of all the knowledge that a student may acquire on so prolific a subject of investigation as fever especially where he has enjoyed the unrivalled ad-
